Vital Force 'Phantom Atoms' Accelerate Pinto Bean Seedling Development and Increase Vitality

Experiments conducted by Dr. W.C. Levengood, Pinelandia Biophysics Lab, Michigan, 2002

In a 7 day seedling development study the “Phantom Atom” of the element Zinc produced robust pinto bean seedlings. 75% of the seedlings watered with the PA of Zinc developed to heights of 30cm or greater while in the seedling control sample only 14% of the seedlings reached a height of 30cm.

We compared the germination and development of seeds watered with several different Periodic Table element “Phantom Atoms” to a control sample. The PA of Zinc demonstrated the best effect on the overall vitality of the pinto bean seedlings. They demonstrated more vigorous growth, stronger and straighter stems, more uniform height distribution and hardy root structure. The Phantom Atom of Lithium demonstrated better results than the control sample but the PA of Zinc produced dramatically superior results.

Pinto Bean Seedling Growth after 3 days

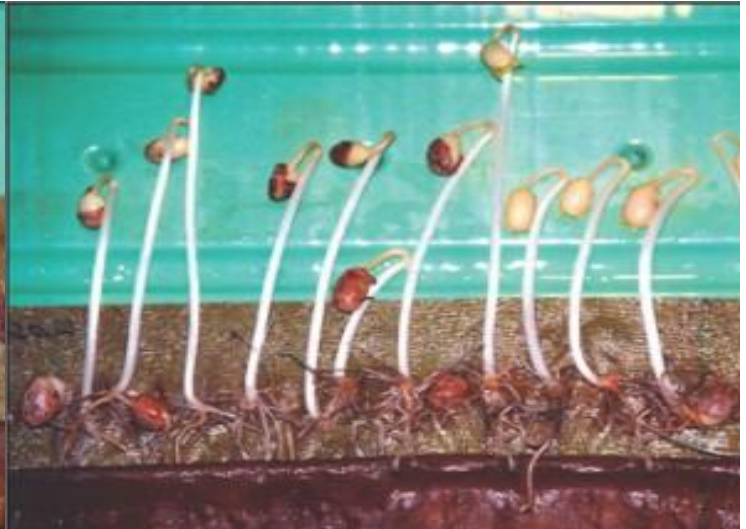

Beans Control 3 Day Germination

Note: Control Sample

- The germination rate is slower
- The root system is less vigorous
- The sprouts are not well developed

Beans Zinc 3 Day Germination

Note: Energy Imprint (PA) of Zinc

- Increased germination
- Increased root growth
- Significant vitality of the sprout

Pinto Bean Seedling Growth after 7 days

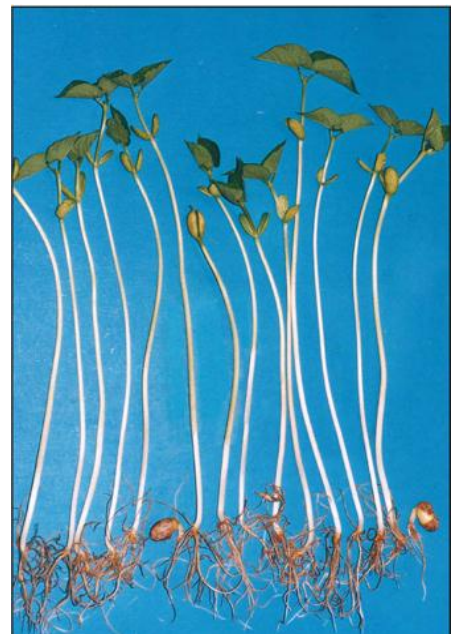

Beans Control 7 Day Germination

Note: Control Sample

- Fewer seeds germinated
- Less Vigorous root development
- Significantly diminished development
- 14% of seedlings reached 30cm

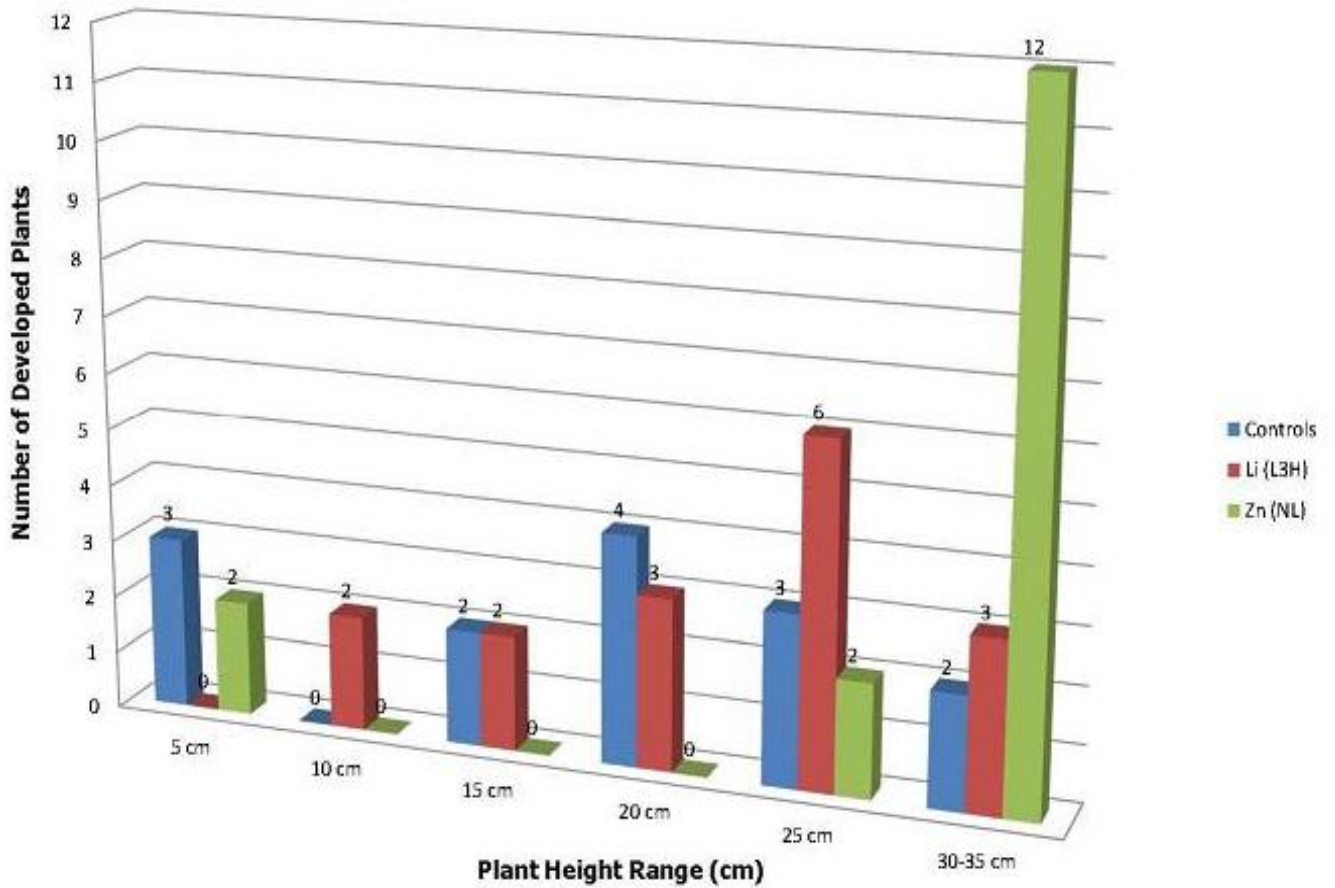

Beans Zinc 7 Day Germination

Note: Energy Imprint (PA) of Zinc

- Increased germination
- Stronger root development
- Vigorous and uniform seedling development
- 75% of seedlings reached 30cm or greater
